

The function of the generator blade guard

Overview

This guard protects the operator by placing a barrier between the danger area and the operator. The main parts of a generator are the frame, engine, fuel system, starter mechanism, lubrication system, alternator, voltage regulator, enclosure, control panel, exhaust, battery, and cooling system. Machines can cause a variety of injuries ranging from minor abrasions, burns or cuts to severe injuries such as fractures, lacerations, crushing injuries or even amputation. A blade guard is a protective barrier on power tools like saws and grinders that covers part of the spinning blade or wheel, moves out of the way during a cut, and helps prevent accidental contact, debris throw, and kickback injuries while preserving visibility and proper support of the workpiece. It runs on fuel, such as gasoline, diesel, or propane, and converts chemical energy into mechanical energy. The type of operation, the size or shape of stock, the method of handling, the physical layout of the work area, the type of material, and production requirements or limitations will help to determine the appropriate safeguarding method for the individual machine.

How does a blade guard work?

By enclosing the blade and providing an opaque barrier, the guard prevents the operator from coming into contact with the blade. Additionally, in some cases, the guard has a dust chute built in to help ...
