

What will happen if solar energy continues to generate electricity

Overview

We identified two key factors that will drive the rapid expansion of solar energy: its affordability and swift construction timeline. The construction of a solar farm usually takes just one year to complete. In comparison, offshore wind farms can take up three years to construct. The three main dispatchable sources of electricity generation (natural gas, coal, and nuclear) accounted for 75% of total generation in 2025, but we expect the share of generation from these sources will fall to about 72% in 2027. The reduction of fossil fuel consumption would substantially decrease. The advancement and adoption of solar photovoltaic (PV) energy has undergone a meteoric rise in the last few decades. It has been the world's fastest-growing energy source for eighteen consecutive years, while its total share of global energy generation has more than quadrupled over the last seven. The Future of Solar Energy considers only the two widely recognized classes of technologies for converting solar energy into electricity — photovoltaics (PV) and concentrated solar power (CSP), sometimes called solar thermal) — in their current and plausible future forms.

Solar energy

Since solar cells obviously cannot produce electric power in the dark, part of the energy they develop under light is stored, in many applications, for use when light is not available.
